A Proof of Le a 1

We consider the following general optimization problem

$$\min_{\|\mathbf{x}\|_2 \le 1} -\mathbf{x}^\top \mathbf{y} + \gamma \|\mathbf{x}\|_1. \tag{15}$$

Before we proceed, we need the following lemma.

Le a 6 The solution to the optimization problem

$$\min_{x} \frac{1}{2}(x-y)^2 + \gamma |x|$$

is given by

$$P_{\gamma}(y) = \begin{cases} 0, & \text{if } |y| \leq \gamma; \\ sign(y)(|y| - \gamma), & \text{otherwise.} \end{cases}$$

where $P_{\gamma}(\cdot)$ is the soft-thresholding operator defined in (7) (Donoho, 1995).

The proof of Lemma 6 can be found in (Duchi & Singer, 2009). Based on the above lemma, it is easy to verify that

$$\min_{x} \frac{1}{2} (x - y)^2 + \gamma |x| = \begin{cases} \frac{y^2}{2}, & \text{if } |y| \le \gamma; \\ \gamma |y| - \frac{\gamma^2}{2}, & \text{otherwise.} \end{cases}$$
(16)

First, we consider the case $||y||_{\infty} \leq \gamma$. Then, it is easy to verify that

$$\mathbf{0} \in \operatorname*{argmin}_{\mathbf{x}} - \mathbf{x}^{\top} \mathbf{y} + \gamma \| \mathbf{x} \|_{1}.$$

Since $\|\mathbf{0}\|_2 \le 1$, **0** is also an optimal solution to (15).

Next, we consider the case $||y||_{\infty} > \gamma$. Following the standard analysis of convex optimization (Boyd & Vandenberghe, 2004), the Lagrange dual

function $q(\mu)$ of (15) is given by

$$g(\mu) = \min_{\mathbf{x}} -\mathbf{x}^{\top} \mathbf{y} + \gamma \|\mathbf{x}\|_{1} + \mu(\|\mathbf{x}\|_{2}^{2} - 1)$$

$$= \min_{\mathbf{x}} 2\mu \left(\frac{1}{2} \|\mathbf{x} - \frac{\mathbf{y}}{2\mu}\|_{2}^{2} + \frac{\gamma}{2\mu} \|\mathbf{x}\|_{1}\right) - \frac{\|\mathbf{y}\|_{2}^{2}}{4\mu} - \mu$$

$$= 2\mu \left(\sum_{i} \min_{x_{i}} \frac{1}{2} \left(x_{i} - \frac{y_{i}}{2\mu}\right)^{2} + \frac{\gamma}{2\mu} |x_{i}|\right) - \frac{\|\mathbf{y}\|_{2}^{2}}{4\mu} - \mu$$

$$\stackrel{(16)}{=} 2\mu \left(\sum_{i:|y_{i}| \leq \gamma} \frac{y_{i}^{2}}{8\mu^{2}} + \sum_{i:|y_{i}| > \gamma} \left(\frac{\gamma |y_{i}|}{4\mu^{2}} - \frac{\gamma^{2}}{8\mu^{2}}\right)\right)$$

$$- \frac{\|\mathbf{y}\|_{2}^{2}}{4\mu} - \mu$$

$$= \sum_{i:|y_{i}| > \gamma} \left(\frac{\gamma |y_{i}|}{2\mu} - \frac{\gamma^{2}}{4\mu} - \frac{y_{i}^{2}}{4\mu}\right) - \mu$$

$$= -\frac{\sum_{i:|y_{i}| > \gamma} (|y_{i}| - \gamma)^{2}}{4\mu} - \mu = -\frac{\|P_{\gamma}(\mathbf{y})\|_{2}^{2}}{4\mu} - \mu.$$

So, the Lagrange dual problem is

$$\max_{\mu \ge 0} -\frac{\|P_{\gamma}(\mathbf{y})\|_2^2}{4\mu} - \mu$$

and the optimal dual solution is

$$\mu_* = \frac{\|P_{\gamma}(\mathbf{y})\|_2}{2}.$$

Following the standard analysis (Boyd & Vandenberghe, 2004, Section 5.5.5), the optimal primal solution is

$$\begin{split} \mathbf{x}_* &= \underset{\mathbf{x}}{\operatorname{argmin}} \, \frac{1}{2} \left\| \mathbf{x} - \frac{\mathbf{y}}{2\mu_*} \right\|_2^2 + \frac{\gamma}{2\mu_*} \|\mathbf{x}\|_1 \\ &= \frac{1}{\|P_{\gamma}(\mathbf{y})\|_2} P_{\gamma}(\mathbf{y}). \end{split}$$

B Proof of Le a

We first consider the case $sign(\mathbf{x}_k^{\top}\mathbf{u}) = 1$, i.e.,

$$\mathbf{x}_k^\top \frac{\mathbf{u}}{\|\mathbf{u}\|_2} > \delta_k.$$

Then, we have

$$\mathbf{x}_*^{\top} \frac{\mathbf{u}}{\|\mathbf{u}\|_2} = \mathbf{x}_k^{\top} \frac{\mathbf{u}}{\|\mathbf{u}\|_2} + (\mathbf{x}_* - \mathbf{x}_k)^{\top} \frac{\mathbf{u}}{\|\mathbf{u}\|_2}$$
$$> \delta_k - \|\mathbf{x}_* - \mathbf{x}_k\|_2 \stackrel{(10)}{\geq} 0.$$

Thus,

$$\mathrm{sign}(\mathbf{x}_*^{\top}\mathbf{u}) = \mathrm{sign}\left(\mathbf{x}_*^{\top}\frac{\mathbf{u}}{\|\mathbf{u}\|_2}\right) = 1 = \mathrm{sign}(\mathbf{x}_k^{\top}\mathbf{u}).$$

The case that $sign(\mathbf{x}_k^{\top}\mathbf{u}_i^k) = -1$ can be proved in a similar way.

C Proof of Le ax

First, we have

$$\mathbf{x}_{*}^{\top} \mathbf{E} \left[\mathbf{u}_{i} y_{i} \right] = \mathbf{E} \left[y_{i} \mathbf{x}_{*}^{\top} \mathbf{u}_{i} \right] \stackrel{(4)}{=} \mathbf{E} \left[\theta(\mathbf{x}_{*}^{\top} \mathbf{u}_{i}) \mathbf{x}_{*}^{\top} \mathbf{u}_{i} \right] \stackrel{(5)}{=} \lambda,$$

where we use the fact that for a fixed \mathbf{x}_* , $\mathbf{x}_*^{\top}\mathbf{u}_i$ can be treated as a standard Gaussian random variable.

Consider any vector $\mathbf{x} \perp \mathbf{x}_*$. Since $\mathbf{x}_*^{\top} \mathbf{u}_i$ and $\mathbf{x}^{\top} \mathbf{u}_i$ are two independent Gaussian random variable, y_i is independent from $\mathbf{x}^{\top} \mathbf{u}_i$. Thus, we have

$$\mathbf{x}^{\top} \mathbf{E} \left[\mathbf{u}_i \mathbf{y}_i \right] = \mathbf{E} \left[y_i \mathbf{x}^{\top} \mathbf{u}_i \right] = 0.$$

Then, it is easy to prove Lemma 4 by contradiction.

D Proof of gore

The proof of Theorem 3 is almost identical to that of Theorem 2. The only difference is that in this case, we have

$$\delta_k = \frac{1}{2^{(k-1)/4}},$$

and the total number of calls to the Oracle is upper bounded by

$$m_1 + 2(K-1)t + 2\sqrt{n} \sum_{k=2}^{K} \delta_k m_k$$

$$= m_1 + 2(K-1)t + 2\sqrt{n}m_1 \sum_{k=2}^{K} 2^{3(k-1)/4}$$

$$\leq 2(K-1)t + (3\sqrt{n}2^{3K/4} + 1)m_1.$$

E Proof of Coro ary 1

We first consider the case that

$$m \le 2(K-1)t + (5\sqrt{n}2^{K/2} + 1)m_1,$$

which implies

$$m = O(2^{K/2}\sqrt{n}m_1) = O(2^{K/2}s\sqrt{n}\log n).$$

Thus,

$$\|\mathbf{x}_{K+1} - \widehat{\mathbf{x}}\|_2 = \frac{1}{2^{K/2}} = O\left(\frac{s\sqrt{n}\log n}{m}\right).$$

In the case that

$$m \leq m_1 2^K$$

we have

$$m = O(2^K m_1) = O(2^K s \log n),$$

and thus,

$$\|\mathbf{x}_{K+1} - \widehat{\mathbf{x}}\|_2 = \frac{1}{2^{K/2}} = O\left(\sqrt{\frac{s \log n}{m}}\right).$$

F Proof of Coro ary

The proof is the same as that for Corollary 1.

G Mutp cat ve C ernoff Bound

Quote *. Let $X_1, X_2, ..., X_n$ be independent binary random variables with $\Pr[X_i = 1] = p_i$. Denote $S = \sum_{i=1}^n X_i$ and $\mu = \operatorname{E}[S] = \sum_{i=1}^n p_i$. We have (Angluin & Valiant, 1979)

$$\Pr\left[S \leq (1 - \epsilon)\mu\right] \leq \exp\left(-\frac{\epsilon^2}{2}\mu\right), \text{ for } 0 < \epsilon < 1,$$

$$\Pr\left[S \geq (1 + \epsilon)\mu\right] \leq \exp\left(-\frac{\epsilon^2}{2 + \epsilon}\mu\right), \text{ for } \epsilon > 0.$$

For the second bound, let $t=\frac{\epsilon^2}{2+\epsilon}\mu$, which implies $\epsilon=\frac{t+\sqrt{t^2+8\mu t}}{2\mu}$. Then, with a probability at least e^{-t} , we have

$$S \le \left(1 + \frac{t + \sqrt{t^2 + 8\mu t}}{2\mu}\right)\mu \le 2\mu + 2t.$$
